Best model ARD.

Bayesian approach for ancestral reconstruction. make.simmap function - "performs stochastic mapping using several methods.

For Q="empirical", it first fits a continuous-time reversible Markov model for the evolution of x and then simulates stochastic character histories using that model and the tip states on the tree. This is the same procedure that is described in Bollback (2006), except that simulation is performed using a fixed value of the transition matrix, Q, instead of by sampling Q from its posterior distribution.

For Q="mcmc", it first samples Q nsim times from the posterior probability distribution of Q using MCMC, then it simulates nsim stochastic maps conditioned on each sampled value of Q."

ARD - Q=empirical

```
mtree <- make.simmap(tree,diapause,model="ARD", Q="empirical", pi="estimated")
```

```
## Using pi estimated from the stationary distribution of Q assuming a flat prior.
## pi =
##      1      2      3      4      5
## 0.674758 0.205471 0.021600 0.066550 0.031621
##
## make.simmap is sampling character histories conditioned on the transition matrix
